Table 5: Longitudinal Estimates by College and Cohort: Heterogeneity by Gender and Alternative College Definitions

This table presents data analogous to that in Table 3 by the child's gender, for alternative child income definitions and defining college based on attendance at age 20 instead of our baseline definition (the most attended college between ages 19-22). As in Table 3, we censor any observation with fewer than 50 students. We provide the same set of variables as in Table 3 for each specification (except for median parent incomes by child gender, which were unavailable for this release). We identify the specifications using the following suffixes after the variable names:

Suffix	Robustness Check
_f	Baseline definitions, female children only
_m	Baseline definitions, male children only
_hh	Baseline definitions, part of household earnings
_agi	Alternative child income definition: measure children's income at the household level, including capital gains (Adjusted Gross Income)
_wagse_hh	Alternative child income definition: measure children's income as total household wage earnings (i.e., own plus spousal labor earnings)
_age20	Alternative college definition: assign students to the colleges based on the college they attended at age 20
